 - Hyperparameters & Data Splits

ML Defined, Sort of...

Definitional Thoughts

- A machine learning algorithm is an algorithm that is able to learn from data.
- Mitchell (1997): "A computer program is said to learn from experience E with respect to some class of tasks T and performance measure P, if its performance at tasks in T, as measured by P, improves with experience E."

The Task, T

On Tasks and Examples/Instances

- Scientifically (and philosophically!), ML is interesting: understanding of the principles that underlie intelligence
- Tasks beyond human capacity, e.g., searching the entire web
- Speech recognition, machine translation (MT), etc.
- We teach a machine how to process an example
- An example is a collection of features representing some object or event
- Represented as a vector $x \in \mathbb{R}^n$ where each entry x_i of the vector is a feature.

Classification

On Classification

- Classification: Labeling an input with one or more of k categories
- Binary classification: Picking from k = 2
- Multi-class classification: k > 2
- Multi-label classification: Assign > k to input
- To learn, an algorithm is asked to **produce a function** $f: \mathbb{R}^n \to 1, ..., k$
- When y = f(x), the model assigns an input described by vector x to a category identified by **numeric code** y.

Illustrations

- Binary: Eng. vs. Russian (langid)
- Multi-class: Eng. vs. Russian vs. Swedish,...(langid)
- Multi-label: Eng. & Russian (code-switching)

Regression

- Regression: predict a numerical value given some input
- algorithm is asked to **output a function** $f : \mathbb{R}^n \to \mathbb{R}$.
- Note: Format of output is different from classification

Regression Example

The prediction of the expected claim amount that an insured person will make (used to set insurance premiums).

Experience, E

What is E?

- Supervised ML: The learner *experiences* an entire labeled dataset, to predict label(s)
- Unsupervised ML: Learner experiences a dataset containing many features, then learn useful properties of the structure of this dataset
- In deep learning: Aim to learn the entire probability distribution that generated a dataset explicitly: as in density estimation; implicitly: tasks like synthesis or denoising
- Clustering: dividing the dataset into clusters of similar examples

Word Clustering Example I

Figure: Word clusters (Owoputi et al. ACL 2013).

Measure, P

Accuracy / Error Rate

- For classification, we measure the accuracy of the model
- Accuracy: the proportion of examples for which the model produces the correct output
- Equivalently: measure the error rate
- error rate: the proportion of examples for which the model produces an incorrect output
- Error rate: Referred to as the expected 0-1 loss.
- The 0-1 loss on a particular example is 0 if it is correctly classified and 1 if it is not
- For tasks such as density estimation: use a metric that gives the model a continuous-valued score: average log-probability the model assigns to some examples

Harmonic Mean

- One type of Pythagorean means.
- Appropriate when we need the average of rates
- Expressed as the reciprocal of the arithmetic mean of the reciprocals of observations

1: Harmonic Mean

$$\left(\frac{1^{-1} + 4^{-1} + 4^{-1}}{3}\right)^{-1} = \frac{3}{\frac{1}{1} + \frac{1}{4} + \frac{1}{4}} = \frac{3}{1.5} = 2$$

Precision, Recall, Accuracy & F₁-Score

		Prediction			
		true	false		
p.	positive	а	b		
Gold standard	negative	С	d		

Eval Metrics

Precision: % of positive classifier predictions that are correct: a/a + c

Recall: % of positive cases the classifier caught: a/a + b

Accuracy: % of classifier predictions that are correct: a + d/a + b + c + d

 F_1 Score: The harmonic mean of precision and recall: $2 * \frac{prec*rec}{prec+rec}$

Design Matrix of a Dataset

Data Representation Matrix

- Each row represents an input data example (a vector)
- Each column is a different feature
- Classification: each example (row) is assigned a corresponding label.
- Label: 0 or 1 (e.g., democrat vs. republican for perspective classification)

Matrix Dimensions

A dataset of 100 examples and 5 features: will have a matrix $X \in \mathbb{R}^{100 \times 5}$.

Linear Regression

Linear Regression Set Up

- Goal: Build a system that takes a vector $\mathbf{x} \in \mathbb{R}^n$ and outputs a scalar $y \in \mathbb{R}$ as its output.
- In linear regression, the output is a linear function of the input.
- We call y the gold value (or ground truth) and the predicted value ŷ.
- We define the system as: $\hat{y} = \mathbf{w}^T \mathbf{x}$ where $\mathbf{w} \in \mathbb{R}^n$ is a **vector** of parameters.
- We can think of w as a set of weights that determine how each feature w_i affects the behavior of the system.

Evaluating Model Performance

- Test set: X^(test): matrix of m examples for evaluating how well the model performs
- Labels: y^(test): a vector of regression targets providing the correct value of y for each example in m
- Predictions: $\hat{\mathbf{y}}^{(test)}$: predictions of the model

2: Mean Squared Error (MSE)

$$MSE_{test} = \frac{1}{m} \sum_{i} (\hat{\mathbf{y}}^{(test)} - \mathbf{y}^{(test)})_{i}^{2}.$$

Minimizing Error

Improving Model & Bias Term

- To improve, we want to **minimize error** (*MSE*_{train}) as the model learns from the training data
- We can do this by simply solving where the gradient of MSE_{train} is 0. (See DL Book, p. 108).
- Intercept b: In linear regression, we use one additional parameter-an intercept term b
- This makes it an **affine function** (one composed of a linear function plus a constant), that allows us to move the line: $\hat{y} = \mathbf{w}^{\mathrm{T}} \mathbf{x} + \mathbf{b}$.
- Called bias since the output of the transformation is biased toward being b in the absence of any input
- Practically, this means augmenting x with an extra entry that is always equal to 1. (We optimize that value during training)

Train vs. Test Error

Generalization

- Generalization: We need to perform well on new, previously unseen data
- Test error: in addition to reducing train error, we want to reduce test error
- Making assumptions about how the training and test are collected: help us achieve some generalization
- Statistical learning theory: assume existence of a data generating process
- i.i.d assumptions:
 - Assume examples are **independent** from one another.
 - Assume examples are identically distributed, drawn from the same probability distribution as one another.

Model Capacity, Overfitting & Underfitting

- Goals: 1) Decrease training error & 2) decrease gap between training and test errors.
- Underfitting: model is not able to obtain a 'sufficiently low' error value on training set
- Overfitting gap between training error and test error is 'too large'
- Model capacity: ability of the model to fit a wide variety of functions (from a given hypothesis space). Can be changed by, e.g.:
 - changing its number of input features
 - adding new parameters associated with those features (e.g., use a two degree polynomial [quadratic function] of input features, instead of a one degree polynomial $[x^2vs.x]$).
 - Using non-linear functions

Regularization

Regularization & Weight Decay

- Regularization: a modification to a learning algorithm to reduce its generalization error but not its training error
- Weight decay: we can modify the training criterion for linear regression to include weight decay.
- Below, λ is a value chosen ahead of time that controls the strength of our preference for smaller weights

3: Linear Regression With Weight Decay

$$J(\mathbf{w}) = MSE_{train} + \lambda \mathbf{w}^{\mathrm{T}} \mathbf{w}.$$

Weight Decay

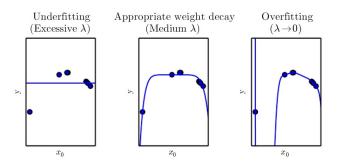

Figure: Linear Regression w/ & w/t Weight Decay. [Goodfellow et al., 2016]

• Multiple other **regularization methods**, some of which particularly developed for deep learning. More on these later . . .

Hyperparameters and Validation Sets

Hyperparameters

- Hyperparameters: settings that control the behavior of a learner
- Examples: (1) the degree of the polynomial used in linear regression and (2) the value of λ used to control weight decay
- hyperparameter are chosen on a validation set
- If chosen on a training set, they will always default to maximum model capacity, resulting in overfitting.
- We construct the validation set exclusively from training data
- As such, we learn hyperparameters from the train split and tune them on the validation split.

More on Validation Set

Data Splitting & Shuffling

- Typical splits: we use 80% of training data as train and 20% as validation (aka development data).
- Another way: 80% train, 10% dev and 10% test
- Data shuffling: if the problem solution does not depend on sequence of instances (e.g., dialect id or sentiment analysis on tweet level)
- NO data shuffling: if sequence is important (e.g., pos tagging, with word-level prediction)
- Benchmarks: With benchmarked data, we must use the exact same data splits as others for comparison
- Test data: always fully blind. We NEVER see test split.

Design of Data Matrix (For Your Reference)

Study_hrs	Ling_bg	Math_bg	Attendance	 Grade
100	6	6	7	 75
120	7	6	9	 85
125	7	8	8	 87
115	8	6	6	 80

Figure: Grade outcome by student study hours, linguistics background, math background, attendance, etc.

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade
	X ₁	X ₂	X ₃	X ₄	X _j	у
X ¹	100	6	6	7		75
X ²	120	7	6	9		85
X ³	125	7	8	8		87
X ⁴	115	8	6	6		80
Xn	•••					

Figure: Each row is an input point (representing a student), and each column is a value of a given **feature**. A row is a **vector**. Last column is the outcome or **gold label** "Y".

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade
	X ₁	X ₂	X ₃	X ₄	X _j	у
X ¹	100	6	6	7		75
X ²	120	7	6	9		85
X ³	125	7	8	8		87
X ⁴	115	8	6	6		80
Xn		•••	•••	•••		

Figure: Row 3 is a data point. We can refer to it as a **feature vector** representing a given student.

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade
	X ₁	X ₂	X ₃	X ₄	X _j	у
X ¹	100	6	6	7		75
X ²	120	7	6	9		85
X ³	125	7	8	8		87
X ⁴	115	8	6	6		80
Xn						

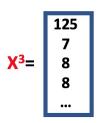

Figure: Row 3 as **feature vector**. $x^3 \in R^{n \times 1}$. Note: We can add one entry to x^3 for **bias** and so it will be $\in R^{n+1 \times 1}$.

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade
	X ₁	X ₂	X ₃	X ₄	X _j	у
X ¹	100	6	6	7		75
X ²	120	7	6	9		85
Χ³	125	7	8	8		87
X ⁴	115	8	6	6		80
Χn						

Figure: **w** is a vector of free parameters that we hope to learn. We can initiate it randomly, or under some distribution (e.g. Gaussian). We also can add a **bias** to it and so it will be $\in \mathbb{R}^{n+1\times 1}$.

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade
	X ₁	X ₂	X ₃	X ₄	X _j	у
X1	100	6	6	7		75
X ²	120	7	6	9		85
X ³	125	7	8	8		87
X ⁴	115	8	6	6		80
Χn						

$$X^{3} = \begin{bmatrix} 125 \\ 7 \\ 8 \\ 8 \\ ... \\ W_{1} \\ W_{2} \\ W_{3} \\ W_{4} \end{bmatrix}$$

$$W^{T} = W^{1} W^{2} W^{3} W^{4} ...$$

Figure: To multiply, we transpose **w** to get w^T . As such, we will have $w^T \in R^{1 \times n + 1}$.

	Study_hrs	Ling_bg	Math_bg	Attendance		Grade	X³=	7 8 8
	X ₁	X ₂	X ₃	X ₄	$\mathbf{X}_{\mathbf{j}}$	у		
X ¹	100	6	6	7		75		W ₁
X ²	120	7	6	9		85		W ₂
X ³	125	7	8	8		87	w =	W ₃ W ₄
X ⁴	115	8	6	6		80		
Xn								

$$\tilde{y} = w^T x + b$$
 $w^T = w^1 w^2 w^3 w^4 ...$

Figure: Now we can predict. The problem is that we do not know the best values of our weights. We can either get these values **analytically** or learn them e.g., via **gradient descent**.
